

**GT 4.2.0 Reliable File Transfer (RFT)
Service: System Administrator's Guide**

DRAFT

GT 4.2.0 Reliable File Transfer (RFT) Service: System Administrator's Guide

Introduction

This guide contains advanced configuration information for system administrators working with RFT. It provides references to information on procedures typically performed by system administrators, including installation, configuring, deploying, and testing the installation.

Important

This information is in addition to the basic Globus Toolkit prerequisite, overview, installation, security configuration instructions in [Installing GT 4.2.0](#). Read through this guide before continuing!

RFT is used to perform third-party transfers across GridFTP servers. It uses a database to store its state periodically so the transfers can be recovered from any failures. RFT uses standard grid security mechanisms for authorization and authentication of the users. In order to effectively use RFT you should have installed and configured a database with RFT database schemas and have the necessary security infrastructure in place to perform a 3rd party transfer.

Chapter 1. Building and Installing

RFT is built and installed as part of a default [GT 4.2.0 installation](#). No extra installation steps are required for this component.

The following are specialized instructions for advanced developers who want to deploy latest code from CVS:

Build RFT from CVS:

1. Configure your CVSROOT to point to the globus CVS location.

2. Run:

```
cvs co ws-transfer
```

3. Run:

```
cd ws-transfer/reliable
```

4. Set GLOBUS_LOCATION to point to your globus installation.

5. Run:

```
ant deploy
```

Chapter 2. Configuring RFT

1. Configuration overview

RFT has the following prerequisites:

- [Java WS Core](#) - This is built and installed in a [Installing GT 4.2.0](#).
- A host certificate (see [Installing GT 4.2.0](#)).
- [GridFTP](#) - GridFTP performs the actual file transfer and is built and installed in a [Installing GT 4.2.0](#).
- PostgreSQL - PostgreSQL is used to store the state of the transfer to allow for restart after failures. The interface to PostgreSQL is JDBC, so any DBMS that supports JDBC can be used, although no others have been tested. For instructions on configuring the PostgreSQL database for RFT, see below. .

2. Syntax of the interface

The security of the service can be configured by modifying the [security descriptor](#). It allows for configuring the credentials that will be used by the service, type of authentication and authorization that needs to be enforced. By default, the following security configuration is installed:

- Credentials set for use by the container are used. If they aren't specified, default credentials are used.
- GSI Secure conversation authentication is enforced for all methods.

Note: Changing the required authentication and authorization method will require suitable changes to the clients that contact this service.

To alter the security descriptor configuration, refer to [security descriptor](#). The file to be altered is `$GLOBUS_LOCATION/etc/globus_wsrf_rft/security-config.xml`.

3. Optional configuration: configuring the PostgreSQL database

PostgreSQL (version 7.1 or greater) can be used with RFT but is no longer a requirement. You can either use the packages which came with your operating system (RPMs, DEBs, ...) or build from source. We used PostgreSQL version 7.3.2 for our testing and the following instructions are good for the same.

1. Install PostgreSQL. Instructions on how to install/configure PostgreSQL can be found [here](#)¹.
2. Configure the postmaster daemon so that it accepts TCP connections. This can be done by adding the "-o -i" switch to the postmaster script (This is either the init.d script found in `/etc/init.d/postgresql` or `/var/lib/`, depending on how you installed PostgreSQL). Follow the instructions [here](#)² to start the postmaster with the -i option.
3. You will now need to create a PostgreSQL user that will connect to the database. This is usually the account under which the container is running. You can create a PostgreSQL user by running the following command: `su postgres; createuser globus`. If you get the following error: `psql: could not connect to`

¹ <http://www.postgresql.org/docs/manuals/>

² <http://www.postgresql.org/docs/7.4/static/postmaster-start.html>

server: No such file or directory Is the server running locally and accepting connections on Unix domain socket "/tmp/.s.PGSQL.5432"? this generally means that either your postmaster is not started with the -i option or you didn't restart the postmaster after the above mentioned step.

4. Now you need to set security on the database you are about to create. You can do it by following the steps below:

```
sudo vi /var/lib/pgsql/data/pg_hba.conf and append the following line to the file:
```

```
host rftDatabase "username" "host-ip" 255.255.255.255 md5 Note: use crypt instead of md5 if you are using PostgreSQL 7.3 or earlier.
```

```
sudo /etc/init.d/postgresql restart
```

5. To create the database that is used for RFT run (as user globus): `createdb rftDatabase`.
6. To populate the RFT database with the appropriate schemas run: `psql -d rftDatabase -f $GLOBUS_LOCATION/share/globus_wsrft_rft/rft_schema.sql`. Now that you have created a database to store RFT's state, the following steps configure RFT to find the database:
7. Open `$GLOBUS_LOCATION/etc/globus_wsrft_rft/jndi-config.xml`.
8. Find the `dbConfiguration` section under the `ReliableFileTransferService <service>` section.
9. Change the `connectionString` to point to the machine on which you installed PostgreSQL and to the name of the database you used in step 2. If you installed PostgreSQL on the same machine as your Globus install, the default should work fine for you.
10. Change the `userName` to the name of the user who owns/created the database and do the same for the password (it also depends on how you configured your database).
11. Don't worry about the other parameters in the section. The defaults should work fine for now.
12. Edit the configuration section under `ReliableFileTransferService`. There are two values that can be edited in this section:
13.
 - `backOff`: Time in seconds you want RFT to backoff before a failed transfer is retried by RFT. The default should work fine for now.
 - `maxActiveAllowed`: This is the number of transfers the container can do at given point. The default should be fine for now.

4. Optional configuration: configuring the MySQL database

If you prefer MySQL to Postgres or derby you can use it with RFT instead. Instructions on how to this can be found at [here](http://www.globus.org/toolkit/docs/4.2/4.2.0/data/rft/admin/rft-admin-mysql.html).³

³ <http://www.globus.org/toolkit/docs/4.2/4.2.0/data/rft/admin/rft-admin-mysql.html>

5. RFT auto-registration with default WS MDS Index Service

With a default GT 4.2.0 installation, the RFT service is automatically registered with the default WS MDS Index Service running in the same container for monitoring and discovery purposes.

There is a jndi resource defined in `$GLOBUS_LOCATION/etc/globus_wsrf_rft/jndi-config.xml` as follows :

```
<resource name="mdsConfiguration"
  type="org.globus.wsrfl.impl.servicegroup.client.MDSConfiguration">
  <resourceParams>
    <parameter>
      <name>reg</name>
      <value>true</value>
    </parameter>
    <parameter>
      <name>factory</name>
      <value>org.globus.wsrfl.jndi.BeanFactory</value>
    </parameter>
  </resourceParams>
</resource>
```

To configure the automatic registration of RFT to the default WS MDS Index Service, change the value of the parameter `<reg>` as follows:

- `true` turns on auto-registration; this is the default in GT 4.2.0.
- `false` turns off auto-registration.

5.1. Configuring resource properties

By default, the following resource properties (from the RFT Factory Resource) are sent to the default Index Service:

- `ActiveResourceInstances`: A dynamic resource property of the total number of active RFT resources in the container at a given point of time.
- `TotalNumberOfTransfers`: A dynamic resource property of the total number of transfers/deletes performed since the RFT service was deployed in this container.
- `TotalNumberOfActiveTransfers`: A dynamic resource property of the number of active transfers across all rft resources in a container at a given point of time.
- `TotalNumberOfBytesTransferred`: A dynamic resource property of the total number of bytes transferred by all RFT resources created since the deployment of the service.
- `RFTFactoryStartTime`: Time when the service was deployed in the container. Used to calculate uptime.
- `DelegationServiceEPR`: The end point reference of the Delegation resource that holds the delegated credential used in executing the resource.

You can configure which resource properties are sent in RFT's registration.xml file, \$GLOBUS_LOCATION/etc/globus_wsrft_rft/registration.xml. The following is the relevant section of the file:

```
<Content xsi:type="agg:AggregatorContent"
  xmlns:agg="http://mds.globus.org/aggregator/types">

  <agg:AggregatorConfig xsi:type="agg:AggregatorConfig">

    <agg:GetMultipleResourcePropertiesPollType
      xmlns:rft="http://www.globus.org/namespaces/2004/10/rft">
      <!-- Specifies that the index should refresh information
        every 60000 milliseconds (once per minute) -->
      <agg:PollIntervalMillis>60000</agg:PollIntervalMillis>

      <!-- specifies that all Resource Properties should be
        collected from the RFT factory -->

      <agg:ResourcePropertyNames>rft:TotalNumberOfBytesTransferred</agg:ResourcePropertyNames>
      <agg:ResourcePropertyNames>rft:TotalNumberOfActiveTransfers</agg:ResourcePropertyNames>
      <agg:ResourcePropertyNames>rft:RFTFactoryStartTime</agg:ResourcePropertyNames>
      <agg:ResourcePropertyNames>rft:ActiveResourceInstances</agg:ResourcePropertyNames>

      <agg:ResourcePropertyNames>rft:TotalNumberOfTransfers</agg:ResourcePropertyNames>

    </agg:GetMultipleResourcePropertiesPollType>
  </agg:AggregatorConfig>
</agg:AggregatorData/>
</Content>
```

6. Registering RFT manually with default WS MDS Index Service

If a third party needs to register an RFT service manually, see [Registering with mds-servicegroup-add](#) in the WS MDS Aggregator Framework documentation.

Chapter 3. Using MySQL

RFT in 4.2.0 works with MySQL database. A MySQL schema file is provided at `$GLOBUS_LOCATION/share/globus_wsrft_rft/rft_schema_mysql.sql`. You will need to download MySQL drivers (MySQL connector/J 3.1 and not 3.0) from [here](#)¹ and copy the driver jar to `$GLOBUS_LOCATION/lib`. You will also need to make following changes :

1. Create a RFT Database and populate it with mysql schema.

```
mysqladmin -h hostname create rftDatabase -p

mysql -h hostname -D rftDatabase

source share/globus_wsrft_rft/rft_schema_mysql.sql
```

Note

If you are using older (earlier than 4.1) versions of MySQL, you will need to use the schema `$GLOBUS_LOCATION/share/globus_wsrft_rft/rft_schema_mysql_pre4.0.sql` to make RFT work. See [Bug 3633](#)² for more details.

2. Edit `$GLOBUS_LOCATION/etc/globus_wsrft_rft/jndi-config.xml` and change the following values:
 - for *connectionString*, change `jdbc:postgresql://host/rftDatabase` to `jdbc:mysql:///rftDatabase`
 - for *driverName*, change `org.postgresql.Driver` to `com.mysql.jdbc.Driver`
 - and change the *userName* and *password* to whatever was set when users were created for MySQL.

¹ <http://dev.mysql.com/downloads/connector/j/3.1.html>

² http://bugzilla.globus.org/globus/show_bug.cgi?id=3633

Chapter 4. Deploying

RFT is deployed as part of a [standard toolkit installation](#).

1. Deploying into Tomcat

RFT has been tested to work without any additional setup when deployed into Tomcat. Please follow these [basic instructions](#) to deploy GT4 services into Tomcat.

Note

You need to configure the GT4 install with the needed RFT configuration (like database configuration, etc) before you deploy into Tomcat.

DRAFT

Chapter 5. Testing

1. Set `$GLOBUS_LOCATION` to point to your Globus install.
2. Start a gridftp server on the machine you are running the tests on the default port. This can be done by running:

```
$GLOBUS_LOCATION/sbin/globus-gridftp-server -p 2811 &
```
3. Start the container with RFT deployed in it.
4. Edit `$GLOBUS_LOCATION/share/globus_wsrf_rft_test/test.properties`. Put in appropriate values for properties like:

- `authzValue` (self or host),
- `HOST` (host IP of container),
- `PORT` (port on which the container is listening),
- `sourceHost` and `destinationsHost` (hostnames of GridFTP servers).

The default values will work fine if you are running the tests with a standard stand-alone container started with user credentials (self authorization is done in this case).

- If the container is started using host credentials, change `authzValue` to `host`.
 - If the GridFTP servers you are using for your testing are started as user, you need to supply subject names of the users in `sourceSubject` and `destinationSubject` for authorization with GridFTP servers.
 - If both the source and destination servers are started as one user, you can just fill in the user's subject in the `subject` field of `test.properties`.
 - *If you are getting Authentication/Authorization Failures because of mismatched subject names, then your `authzVal` and `authType` (uses transport security by default) need to be changed, depending on how you started the container. If you started the container with the `-nosec` option, then you need to change `authType` to `GSI_MESSAGE, PROTOCOL` to `http` and `PORT` to `8080`.*
5. The `*.xfr` files in `$GLOBUS_LOCATION/share/globus_wsrf_rft_test/` are the transfer files that will be used in the tests. Again, the default values work fine if you followed the instructions so far.
 6. Run the following command, which will run all the RFT unit tests:

```
ant -Dtests.jar=$GLOBUS_LOCATION/lib/globus_wsrf_rft_test.jar -f share/globus_wsrf_rft_
```

7. Run the following command to generate the test reports in html form:

```
ant -f share/globus_wsrf_rft_test/runtests.xml generateTestReport
```

Chapter 6. Security Considerations

1. Reliable Transfer Service (RFT) Security Considerations

1.1. Permissions of service configuration files

The service configuration files such as `jndi-config.xml` and `server-config.wsdd` (located under `etc/<gar>/` directory) contain private information such as database passwords and usernames. Ensure that these configuration files are only readable by the user that is running the container.

The deployment process automatically sets the permissions of `jndi-config.xml` and `server-config.wsdd` as user readable only. However, this might not work correctly on all platforms and this does not apply to any other configuration files.

1.2. Access of information stored in the database

RFT stores the transfer requests in a database. Proper security measures need to be taken to protect the access of the data by granting/revoking appropriate permissions on tables that are created for RFT use and other steps that are appropriate and consistent with site specific security measures.

1.3. Permissions of persistent data

RFT uses the subscription persistence API from the GT4 core to store all of its subscription data under the `~/ .globus/persisted` directory. Ensure that the entire `~/ .globus/persisted` directory is only readable by the user running the container.

Chapter 7. Debugging

The following information is about sys admin logging in Java WS Core (on which RFT is built).

1. Logging in Java WS Core

The following information applies to Java WS Core and all services built on Java WS Core.

Java WS Core server side has two types of loggers. One logger is used for development logging and by default writes to standard out. The other logger includes system administration information and is [CEDPs best practices](#)¹ compliant.

On client side, only developer logging is available and is configured using `log4j.properties`.

1.1. Development Logging in Java WS Core

The following information applies to Java WS Core and those services built on it.

Logging in the Java WS Core is based on the [Jakarta Commons Logging](#)² API. Commons Logging provides a consistent interface for instrumenting source code while at the same time allowing the user to plug-in a different logging implementation. Currently we use [Log4j](#)³ as a logging implementation. Log4j uses a separate configuration file to configure itself. Please see Log4j documentation for details on the [configuration file format](#)⁴.

1.1.1. Configuring server side developer logs

Server side logging can be configured in `$GLOBUS_LOCATION/container-log4j.properties`, when the container is stand alone container. For tomcat level logging, refer to [Logging for Tomcat](#)⁵. The logger `log4j.appender.A1` is used for developer logging and by default writes output to the system output. By default it is set for all warnings in the Globus Toolkit package to be displayed.

Additional logging can be enabled for a package by adding a new line to the configuration file. Example:

```
#for debug level logging from org.globus.package.FooClass
log4j.category.org.globus.package.name.FooClass=DEBUG
#for warnings from org.some.warn.package
log4j.category.org.some.warn.package=WARN
```

1.1.2. Configuring client side developer logs

Client side logging can be configured in `$GLOBUS_LOCATION/log4j.properties`. The logger `log4j.appender.A1` is used for developer logging and by default writes output to the system output. By default it is set for all warnings in the Globus Toolkit package to be displayed.

¹ <http://cedps.net/index.php/LoggingBestPractices>

² <http://jakarta.apache.org/commons/logging/>

³ <http://logging.apache.org/log4j/>

⁴ [http://logging.apache.org/log4j/docs/api/org/apache/log4j/PropertyConfigurator.html#doConfigure\(java.lang.String,org.apache.log4j.spi.LoggerRepository\)](http://logging.apache.org/log4j/docs/api/org/apache/log4j/PropertyConfigurator.html#doConfigure(java.lang.String,org.apache.log4j.spi.LoggerRepository))

⁵ <http://tomcat.apache.org/tomcat-5.5-doc/logging.html>

1.2. Configuring system administration logs

The specific logger to edit will be `log4j.logger.sysadmin` in `$GLOBUS_LOCATION/container-log4j.properties`. There you can configure the following properties:

```
log4j.appender.infoCategory=org.apache.log4j.RollingFileAppender
log4j.appender.infoCategory.Threshold=INFO
log4j.appender.infoCategory.File=var/containerLog
log4j.appender.infoCategory.MaxFileSize=10MB
log4j.appender.infoCategory.MaxBackupIndex=2
```

Above implies the logging file is rolling with each file size limited to 10MB and the logging information is stored in `$GLOBUS_LOCATION/var/containerLog`.

1.3. Sample log file

The [sample log file](#)⁶ contains many log entries for various scenarios in the Java WS container.

2. Specifying verbose error messages

Edit `$GLOBUS_LOCATION/container-log4j.properties` and add the following line to it:

```
log4j.category.org.globus.transfer=DEBUG
```

For even more verbosity add

```
log4j.category.org.globus.ftp=DEBUG
```

, which will also print out GridFTP messages.

⁶ <http://www.globus.org/toolkit/docs/4.2/4.2.0/common/javawscore/sample-container-log.txt>

Chapter 8. Troubleshooting

For a list of common errors in GT, see [Error Codes](#).

1. Errors

Table 8.1. Reliable File Transfer (RFT) Errors

Error Code	Definition	Possible Solutions
Error creating RFT Home: Failed to connect to database ... Until this is corrected all RFT request will fail and all GRAM jobs that require staging will fail	This occurs when you start the container if RFT is not configured properly to talk to a PostgreSQL database.	The usual cause is that Postmaster is not accepting TCP connections, which means that you must restart Postmaster with the <code>-i</code> option (see Configuring RFT).

2. RFT fault-tolerance and recovery

RFT uses PostgreSQL to check-point transfer state in the form of restart markers and recover from transient transfer failures, using retry mechanism with exponential backoff, during a transfer. RFT has been tested to recover from source and/or destination server crashes during a transfer, network failures, container failures (when the machine running the container goes down), file system failures, etc. RFT Resource is implemented as a PersistentResource, so ReliableFileTransferHome gets initialized every time a container gets restarted. Please find a more detailed description of fault-tolerance and recovery in RFT below:

- **Source and/or destination GridFTP failures:** In this case RFT retries the transfer for a configurable number of maximum attempts with exponential backoff for each retry (the backoff time period is configurable also). If a failure happens in the midst of a transfer, RFT uses the last restart marker that is stored in the database for that transfer and uses it to resume the transfer from the point where it failed, instead of restarting the whole file. This failure is treated as a container-wide backoff for the server in question. What this means is that all other transfers going to/from that server, across all the requests in a container, will be backed off and retried. This is done in order to prevent further failures of the transfers by using knowledge available in the database.
- **Network failures:** Sometimes this happens due to heavy load on a network or for any other reason packets are lost or connections get timed out. This failure is considered a transient failure and RFT retries the transfer with exponential backoff for that particular transfer (and not the whole container, as with the source and/or destination GridFTP failures).
- **Container failures:** These type of failures occur when the machine running the container goes down or if the container is restarted with active transfers. When the container is restarted, it restarts ReliableTransferHome, which looks at the database for any active RFT resources and restarts them.

2.1. Failure modes that are not addressed:

- Running out of disk space for the database.

Chapter 9. Usage statistics collection by the Globus Alliance

1. Usage statistics sent by RFT

The following usage statistics are sent by default in a UDP packet at the end of life time of each RFT Resource (or when a RFT resource is destroyed).

- Total number of files transferred by RFT since RFT was installed
- Total number of bytes transferred by RFT since RFT was installed
- Total number of files transferred in this RFT Resource
- Total number of bytes transferred in this RFT Resource
- Creation time of this RFT Resource
- Factory Start Time

We have made a concerted effort to collect only data that is not too intrusive or private, and yet still provides us with information that will help improve the RFT component. Nevertheless, if you wish to disable this feature, please see the "Usage Statistics Configuration" section of [Configuring Java WS Core](#) for instructions.

Also, please see our [policy statement](#)¹ on the collection of usage statistics.

GT 4.2.0 Reliable File Transfer (RFT) Service: User's Guide

DRAFT

GT 4.2.0 Reliable File Transfer (RFT) Service: User's Guide

Introduction

RFT is the Reliable Transfer Service. It allows clients to submit URL transfer requests to a persistent service which will perform the transfers on behalf of the client. RFT Service implementation in GT 4.2.0 uses standard SOAP messages over HTTP to submit and manage a set of 3rd party GridFTP transfers and to delete files using GridFTP. The user creates a RFT resource by submitting a list of URL pairs of files that need to be transferred/deleted to RFT Factory service. The user also specifies the time to live for the resource the user is creating to a GT 4.2.0 Container in which RFT is deployed and configured. The resource is created after the user is properly authorized and authenticated. RFT service implementation exposes operations to control and manage the transfers (the resource). The operations exposed by both RFT factory and RFT service are briefly described below. The resource the user created also exposes the state of the transfer as a resource property to which the user can either subscribe for changes or poll for the changes in state periodically using standard command line clients.

DRAFT

Chapter 1. Using RFT

The Java clients, **rft** and **rft-delete** commands are available for very simple transfers. For more options, use the programming instructions [here](#).

1. globus-crft

Beginning with 4.2.0, RFT also offers a new C client, **globus-crft**.

1.1. Submitting A Transfer

To submit a transfer request the user must first create a 'transfer file'. Each line of this ASCII text file is a source/destination URL pair. There can be any number of of lines per file. An example file follows:

```
gsiftp://localhost:2811/etc/group gsiftp://localhost:2811/tmp/test_crft
gsiftp://ftp.globus.org:2811/pub/README gsiftp://myhost.here/home/user/file
```

This file requests two transfers. The first will use the GridFTP server running on the localhost to transfer /etc/group to /tmp/test_crft. The second will transfer the file /pub/README on ftp.globus.org to the file /home/user/file located on myhost.here

Once the transfer file is created globus-crft can be used in a variety of ways to transfer a file. The most simple is the blocking transfer:

```
% globus-crft -c -s -m -vb -f <transfer file> -e <container contact string>
```

Looking at each option individually, this command line does the following

-c Create a new RFT server., **-s** Submit the transfer request. Since RFT is a 2 phase commit we allow the client the ability to do them in separate stages, however it is expected that the vast majority of the time -c and -s will be used together.

-m Monitor the transfers. When this option is used the client will block until all transfers have completed. It monitors the status of the transfers along the way and can report it to the user.

-vb Display verbose output. This just increases the level of diagnostic messages sent to stdout. When combined with -m it will allow the user to see the status of a transfer.

-f <transfer file> This option is a pointer to the transfer file described above.

-e <container contact strings> The contact string is in the following form:

```
https://hostname.com:8443/wsrf/services/
```

The strings ___ and ___ will be appended to the given string in order for the client to interact with that containers delegation service and RFT service.

1.2. Non-blocking Transfer

The client can do non-blocking RFT submission. It can submit an RFT request and then terminate, returning later to monitor the status of the request. To accomplish this the client saves the EPR of the newly created RFT service to disk.

```
% globus-crft -c -s -f <transfer file> -e <container contact string> \  
-ef <epr output file>
```

At some point later the client uses this same file to monitor the state of the transfer:

```
% globus-crft -ef <epr input file> --getOverallStatus
```

Note

Note that in both cases the option `-ef` is used. In the first case, since the `-c` option is used, we are creating a new service and the `-ef` option is a pointer to an output file. In all cases where `-c` is not used, the `-ef` switch is a pointer to an input file.

1.3. Cleaning Up

Once a transfer request completes, the user should destroy the resources associated with it. If the user stored the EPR of the service it created, this can be done with:

```
% globus-crft -ef <epr input file> --destroy
```

1.4. More

For a list of more options run:

```
globus-crft --help
```

RFT Commands

DRAFT

Name

rft -- Submit and monitor a 3rd party GridFTP transfer

rft

Tool description

Submits a transfer to the Reliable File Transfer Service and prints out the status of the transfer on the console.

Command syntax and options

```
rft [-h <host-ip of the container defaults to localhost>
-r <port, defaults to 8080>
-l <lifetime for the resource default 60mins>
-m <security mechanism. 'msg' for secure message or 'conv' for
  secure conversation and 'trans' for transport. Defaults to
  secure transport.>
-p <protection type, 'sig' signature and 'enc' encryption,
  defaults to signature >
-z <authorization mechanism can be self or host. default self>
-file <file to write EPR of created Reliable File Transfer Resource]>
-f <path to the file that contains list of transfers>
```

This is a sample transfer file that the command-line client will be able to parse. It can also be found in **\$GLOBUS_LOCATION/share/globus_wsrf_rft_client/** along with other samples for directory transfers and deletes (lines starting with # are comments):

This option when it is set to true means to perform transfer in binary form, if it is set to false transfer is done in ASCII. Default is binary.

```
true
#Block size in bytes that is transferred. Default is 16000 bytes.
16000
```

```
#TCP Buffer size in bytes
```

```
#Specifies the size (in bytes) of the TCP buffer to be used by the underlying
ftp data channels. This is critical to good performance over the WAN. Use the
bandwidth-delay product as your buffer size.
```

```
16000
```

```
#Notpt (No thirdPartyTransfer): turns third-party transfers off is this option
is set to false (on if set to true).
```

```
Site firewall and/or software configuration may prevent a connection
between the two servers (a third party transfer). If this is the case,
RFT will "relay" the data. It will do a GET from the source and a PUT to
the destination. This obviously causes a performance penalty, but will allow
you to complete a transfer you otherwise could not do.
```

```
false
```

```
#Number of parallel streams: Specifies the number of parallel data connections
that should be used.
```

1

#Data Channel Authentication (DCAU): Turns off data channel authentication for FTP transfers is set to false.(the default is true to authenticate the data channel).

true

Concurrency of the request: Number of files that you want to transfer at any given point. Default is set to one.

1

#Grid Subject name of the source gridftp server. This is used for Authorization purposes. If the source gridftp server is running with host credentials you can specify "n

/DC=org/DC=doegrids/OU=People/CN=Ravi Madduri 134710

#Grid Subject name of the destination gridftp server. This is used for Authorization purpo

credentials you can specify "null" here. By default Host authorization is done.

/DC=org/DC=doegrids/OU=People/CN=Ravi Madduri 134710

#Transfer all or none of the transfers: This option if set to true will make RFT

to clean up (delete) all the transfers that have been done already if one of the transfe

false

#Maximum number of retries: This is number of times RFT retries a transfer failed with a n

10

#Source/Dest URL Pairs: gsiftp urls of source followed by destination.

If directory is to be recursively transferred the source gsiftp url and destination gsiftp url should end with "/". Currently RFT supports Directory - Directory, File - Directory, File - File transfers. There can be more URL pairs

and all of them use the same options as above for performing the transfer.

gsiftp://localhost:5678/tmp/rftTest.tmp

gsiftp://localhost:5678/tmp/rftTest_Done.tmp

Limitations

This command line client is very simple and does not do any intelligent parsing of various command line options or of the options in the sample transfer file. It works fine if used in the way documented here. For more information on all these options please refer to the [documentation of globus-url-copy](#). Also, please note that the maximum number of transfers the command-line client can process before running out of memory is ~21K with the default JVM heap size, which was 64M in our tests. Please look at [Performance Reports](#)¹ for more details.

¹ ../rft_scalability_3_9_4.doc

Name

globus-crft -- Command-line client to delete files using RFT

globus-crft

Tool description

This distribution contains a client to the RFT service written in C. RFT is the reliable transfer server. It allows clients to submit URL transfer requests to a persistent service which will perform the transfers on behalf of the client.

Options

- `-a | --all-or-none <on | off>` Enable all or none transfer: default off.
- `-con | --concurrent <int>` The number of simultaneous transfers.
- `-C | --cancel` Cancel a transfer.
- `-c | --create` Create a new RFT service.
- `-del | --delete` Delete a URL.
- `-ds | --destination-subject <subject>` The expected domain name of the destination GridFTP server.
- `-d | --destroy` Destroy the server. If used with `-monitor`, wait until completion and then destroy.
- `-D | --done` Return the current status of the transfer in the exit code:
- 0=Done
 - 1=Active
 - 2=Pending
 - 3=Cancelled
 - 4=Failed
- `-ef | --epr-file <path>` Path to the EPR file. If used with `--create` the EPR is written to this location. In all other cases the EPR is read from this location.
- `-ez | --easy` Create, submit, and wait for the transfer to complete. The job is started with some standard options.
- `-e | --factory <contact>` The endpoint to contact when creating a server. Used with `--create`.
- `-f | --transfer-file <path>` A path to a file that contains the source destination URL pairs.
- `-gS | --getStatusSet <int> <int>` Get the status of all the transfer requests in the range.
- `-g | --getStatus <source url>` Get the status of the given source url.

`-h` | `--help` Print usage information.

FIXME - finish converting to variable list:

`-ms` | `--message-security` `<[sig] | [conv] | [trans]>`
Security mechanism. 'msg' for secure message, 'conv' for secure conversation, 'trans' for transport. The default is trans.

`-m` | `--monitor` Wait for the service to complete, and receive status updates.

`-os` | `--getOverallStatus` Get the overall status.

`-p` | `--protection` `<[sig] | [enc]>`
Protection type. 'sig' for signature, 'enc' for encryption. The default is 'sig'.

`-P` | `--parallel` `<int>` The number of parallel sockets to use with each transfer.

`-q` | `--quiet` Write no output.

`-rs` | `--getRequestStatus` Get the request status.

`-r` | `--retries` Number of retries

`-S` | `--subject` `<subject>` The expected domain name of both the source and destination GridFTP servers.

`-ss` | `--source-subject` `<subject>`
The expected domain name of the source GridFTP server.

`-s` | `--submit` Start the RFT service

`-tb` | `--tcp-bs` `<int>` The TCP buffer size to use with each transfer.

`-ttl` | `--termination-time` `<int>`
Set the lifetime of the service.

`-v` | `--version` Print version information.

`-vb` | `--verbose` Display much more output.

`-xi` | `--xml-input` `<path>` Read the request description from the given xml description.

`-xo` | `--xml-output` `<path>` Write the request description to the given file location in xml format.

`-z` | `--authz` `<[self] | [host] | [id <subject>]>`
Authorization. 'self', 'host', or 'id <DN>'.

Limitations

No limitations exist with this command line tool.

Name

rft-delete -- Command-line client to delete files using RFT

rft-delete

Tool description

This command-line tool is used to submit a list of files to be deleted.

Command and options

```
rft-delete [-h <host-ip of the container default localhost>
-r <port, defaults to 8080>
-l <lifetime for the resource default 60mins>
-m <security mechanism. 'msg' for secure message or 'conv' for
  secure conversation and 'trans' for transport. Defaults to
  secure transport.>
-p <protection type, 'sig' signature and 'enc' encryption,
  defaults to signature >
-z <authorization mechanism can be self or host. default self>
-file <file to write EPR of created Reliable File Transfer Resource]>
-f <path to the file that contains list of transfers>
```

This is a sample file that the command line client will be able to parse, and it can also be found in **\$GLOBUS_LOCATION/share/globus_wsrf_rft_client/** along with other samples for directory transfers and deletes (lines starting with # are comments):

```
# Subject name (defaults to host subject)
  /DC=org/DC=doegrids/OU=People/CN=Ravi Madduri 134710
  gsiftp://localhost:5678/tmp/rftTest_Done.tmp
  gsiftp://localhost:5678/tmp/rftTest_Done1.tmp
```

Limitations

No limitations exist with this command line tool.

Chapter 2. Troubleshooting

For a list of common errors in GT, see [Error Codes](#).

1. Troubleshooting tips

- Always have a valid proxy before using command line RFT clients.
- Make sure to provide suitable options to the client, and especially for the Termination time, so that the resource does not get destroyed before finishing the transfers.

2. RFT fault-tolerance and recovery

RFT uses PostgreSQL to check-point transfer state in the form of restart markers and recover from transient transfer failures, using retry mechanism with exponential backoff, during a transfer. RFT has been tested to recover from source and/or destination server crashes during a transfer, network failures, container failures (when the machine running the container goes down), file system failures, etc. RFT Resource is implemented as a PersistentResource, so ReliableFileTransferHome gets initialized every time a container gets restarted. Please find a more detailed description of fault-tolerance and recovery in RFT below:

- **Source and/or destination GridFTP failures:** In this case RFT retries the transfer for a configurable number of maximum attempts with exponential backoff for each retry (the backoff time period is configurable also). If a failure happens in the midst of a transfer, RFT uses the last restart marker that is stored in the database for that transfer and uses it to resume the transfer from the point where it failed, instead of restarting the whole file. This failure is treated as a container-wide backoff for the server in question. What this means is that all other transfers going to/from that server, across all the requests in a container, will be backed off and retried. This is done in order to prevent further failures of the transfers by using knowledge available in the database.
- **Network failures:** Sometimes this happens due to heavy load on a network or for any other reason packets are lost or connections get timed out. This failure is considered a transient failure and RFT retries the transfer with exponential backoff for that particular transfer (and not the whole container, as with the source and/or destination GridFTP failures).
- **Container failures:** These type of failures occur when the machine running the container goes down or if the container is restarted with active transfers. When the container is restarted, it restarts ReliableTransferHome, which looks at the database for any active RFT resources and restarts them.

2.1. Failure modes that are not addressed:

- Running out of disk space for the database.

Chapter 3. Usage statistics collection by the Globus Alliance

1. Usage statistics sent by RFT

The following usage statistics are sent by default in a UDP packet at the end of life time of each RFT Resource (or when a RFT resource is destroyed).

- Total number of files transferred by RFT since RFT was installed
- Total number of bytes transferred by RFT since RFT was installed
- Total number of files transferred in this RFT Resource
- Total number of bytes transferred in this RFT Resource
- Creation time of this RFT Resource
- Factory Start Time

We have made a concerted effort to collect only data that is not too intrusive or private, and yet still provides us with information that will help improve the RFT component. Nevertheless, if you wish to disable this feature, please see the "Usage Statistics Configuration" section of [Configuring Java WS Core](#) for instructions.

Also, please see our [policy statement](#)¹ on the collection of usage statistics.

GT 4.2.0 Reliable File Transfer (RFT) Service: Developer's Guide

DRAFT

GT 4.2.0 Reliable File Transfer (RFT) Service: Developer's Guide

Introduction

RFT Service implementation in GT 4.2.0 uses standard SOAP messages over HTTP to submit and manage a set of 3rd party GridFTP transfers and to delete files using GridFTP. The user creates a RFT resource by submitting a list of URL pairs of files that need to be transferred/deleted to RFT Factory service. The user also specifies the time to live for the resource the user is creating to a GT 4.2.0 container in which RFT is deployed and configured. The resource is created after the user is properly authorized and authenticated. RFT service implementation exposes operations to control and manage the transfers (the resource). The operations exposed by both RFT factory and RFT service are briefly described below. The resource the user created also exposes the state of the transfer as a resource property to which the user can either subscribe for changes or poll for the changes in state periodically using standard command line clients.

Chapter 1. Before you begin

1. RFT Feature Summary

Features new in GT 4.2.0

Supported Features

- Delete files: Delete a set of files/directories on a GridFTP server.
- Exponential Backoff: Configurable exponential back off before a failed transfer is retried.
- Transfer All or None: If this option is set and one of the transfers in the request fails, RFT will stop transferring the remainder of the request and delete the files that were already transferred successfully.
- Transfer Permissions: File permissions are restored at the destination once the file is transferred successfully. This can be configured to throw a fatal error or a transient error depending on whether the GridFTP server supports the MLST command.
- Configurable number of concurrent transfers per container and per request.
- Better error reporting and faults.
- Database purge of the request and transfers after life time expiration.
- Cumulative (aggregate) Resource Properties on the factory provide some statistical information.
- One status Resource Property for the entire transfer.
- Recursive directory transfers and deletes.
- Parallel streams.
- TCP Buffer Size.
- Third-party directory transfers, file transfers and deletes.
- Data channel authentication (DCAU).
- NoTPT option.
- Different subject names for source and destination GridFTP servers for the authorization mechanism.
- Support for binary/ASCII type of transfers.
- Configurable number of retries for failed transfers per request.
- Block Size in bytes.

Deprecated Features

- None

2. Tested platforms

Tested platforms for RFT:

- Linux
 - Fedora Core 1 i686
 - Fedora Core 3 i686
 - RedHat 7.3 i686
 - RedHat 9 x86
 - Debian Sarge x86
 - Debian 3.1 i686
- Mac OS X
 - Mac OS X 10.3, 10.4

Tested containers for RFT:

- Java WS Core container
- Tomcat 5.0.30

3. Backward compatibility summary

Protocol changes since GT 4.0.x

- Added All or None option, maximum attempts, and finishBy to the transfer request
- Not backwards compatible with the OGSi version

API changes since GT 4.0.x

- None

Exception changes since GT 4.0.x

- None

Schema changes since GT 4.0.x

- WSDL changes to work with the new Java WS Core

4. Technology dependencies

RFT depends on the following GT components:

- Java WS Core
- WS Authentication and Authorization

- Delegation Service
- Service Groups
- MDS useful RP

RFT depends on the following 3rd party software:

- Optional : PostgreSQL 7.1 or later. Not tested with 8.0 yet.
- Optional : MySQL

5. Reliable Transfer Service (RFT) Security Considerations

5.1. Permissions of service configuration files

The service configuration files such as `jndi-config.xml` and `server-config.wsdd` (located under `etc/<gar>/` directory) contain private information such as database passwords and usernames. Ensure that these configuration files are only readable by the user that is running the container.

The deployment process automatically sets the permissions of `jndi-config.xml` and `server-config.wsdd` as user readable only. However, this might not work correctly on all platforms and this does not apply to any other configuration files.

5.2. Access of information stored in the database

RFT stores the transfer requests in a database. Proper security measures need to be taken to protect the access of the data by granting/revoking appropriate permissions on tables that are created for RFT use and other steps that are appropriate and consistent with site specific security measures.

5.3. Permissions of persistent data

RFT uses the subscription persistence API from the GT4 core to store all of its subscription data under the `~/ .globus/persisted` directory. Ensure that the entire `~/ .globus/persisted` directory is only readable by the user running the container.

Chapter 2. Usage scenarios

1. Transferring large datasets using GridFTP

RFT is primarily used to reliably transfer large datasets using GridFTP. If you are a developer and would like to use RFT, the following steps would help you to do that.

- Contact the Delegation Factory Service and get an EPR for the Delegation Resource that contains your delegated credential.

```
public static EndpointReferenceType
    delegateCredential(String host, String port) throws Exception {
    ClientSecurityDescriptor desc = new ClientSecurityDescriptor();
    // Credential to sign with, assuming default credential
    GlobusCredential credential = GlobusCredential.getDefaultCredential();
    desc.setGSITransport(Constants.GSI_TRANSPORT)
    Util.registerTransport();
    desc.setAuthz('host');

    String factoryUrl = PROTOCOL + "://" + host + ":"
        + port + SERVICE_URL_ROOT
        + DelegationConstants.FACTORY_PATH;

    // lifetime in seconds
    int lifetime = TERM_TIME * 60;

    // Get the public key to delegate on.
    EndpointReferenceType delegEpr = AddressingUtils
        .createEndpointReference(factoryUrl, null);
    X509Certificate[] certsToDelegateOn = DelegationUtil
        .getCertificateChainRP(delegEpr, desc);
    X509Certificate certToSign = certsToDelegateOn[0];
    return DelegationUtil.delegate(factoryUrl,
        credential, certToSign, lifetime, false,
        desc);
}
```

- Now construct a TransferRequestType Object:

```
TransferType[] transferArray = new TransferType[1];
transferArray[0] = new TransferType();
transferArray[0].setSourceUrl("gsiftp://foo/bar");
transferArray[0].setDestinationUrl("gsiftp://blah/");
RFTOptionsType rftOptions = new RFTOptionsType();
rftOptions.setBinary(true);
// You can set more options like parallel streams, buffer sizes etc
// Refer to Public Interface guide of RFT for more details
TransferRequestType request = new TransferRequestType();
```

```
request.setRftOptions(rftOptions);
request.setTransfer(transferArray);
request.setTransferCredentialEndpoint(delegateCredential(host, port));
```

- Now contact the RFT factory and create an RFT resource:

```
public static EndpointReferenceType createRFT(String rftFactoryAddress,
      BaseRequestType request)
throws Exception {
    endpoint = new URL(rftFactoryAddress);
    factoryPort = rftFactoryLocator
        .getReliableFileTransferFactoryPortTypePort(endpoint);
    CreateReliableFileTransferInputType input =
        new CreateReliableFileTransferInputType();
    //input.setTransferJob(transferType);
    if(request instanceof TransferRequestType) {
        input.setTransferRequest((TransferRequestType)request);
    } else {
        input.setDeleteRequest((DeleteRequestType)request);
    }
    Calendar termTime = Calendar.getInstance();
    termTime.add(Calendar.HOUR, 1);
    input.setInitialTerminationTime(termTime);
    setSecurity((Stub)factoryPort);
    CreateReliableFileTransferOutputType response = factoryPort
        .createReliableFileTransfer(input);

    return response.getReliableTransferEPR();
}
```

- Now contact the RFT service Implementation and call start to actually start the transfer:

```
ReliableFileTransferPortType rft = rftLocator
    .getReliableFileTransferPortTypePort(rftepr);
setSecurity((Stub)rft);

//For secure notifications
subscribe(rft);
System.out.println("Subscribed for overall status");
//End subscription code
Calendar termTime = Calendar.getInstance();
termTime.add(Calendar.MINUTE, TERM_TIME);
SetTerminationTime reqTermTime = new SetTerminationTime();
reqTermTime.setRequestedTerminationTime(termTime);
System.out.println("Termination time to set: " + TERM_TIME
    + " minutes");
SetTerminationTimeResponse termRes = rft
    .setTerminationTime(reqTermTime);
StartOutputType startresp = rft.start(new Start());
```

2. Deleting a set of files and directories using GridFTP

RFT can also be used to delete a set of files and directories using GridFTP server. The following steps depict how to:

- Contact the Delegation Factory Service and get an EPR for the Delegation Resource that contains your delegated credential.

```
public static EndpointReferenceType
    delegateCredential(String host, String port) throws Exception {
    ClientSecurityDescriptor desc = new ClientSecurityDescriptor();
    // Credential to sign with, assuming default credential
    GlobusCredential credential = GlobusCredential.getDefaultCredential();
    desc.setGSITransport(Constants.GSI_TRANSPORT)
    Util.registerTransport();
    desc.setAuthz('host');

    String factoryUrl = PROTOCOL + "://" + host + ":"
        + port + SERVICE_URL_ROOT
        + DelegationConstants.FACTORY_PATH;

    // lifetime in seconds
    int lifetime = TERM_TIME * 60;

    // Get the public key to delegate on.
    EndpointReferenceType delegEpr = AddressingUtils
        .createEndpointReference(factoryUrl, null);
    X509Certificate[] certsToDelegateOn = DelegationUtil
        .getCertificateChainRP(delegEpr, desc);
    X509Certificate certToSign = certsToDelegateOn[0];
    return DelegationUtil.delegate(factoryUrl,
        credential, certToSign, lifetime, false,
        desc);
}
```

- Now construct a DeleteRequestType object:

```
DeleteType[] deleteArray = new DeleteType[1];
deleteArray[0] = new DeleteType();
deleteArray[0].setFile("gsiftp://foo/bar");
DeleteOptionsType deleteOptions = new DeleteOptionsType();
deleteOptions.setSubjectName("SUBJECT-NAME");
DeleteRequestType request = new DeleteRequestType();
request.setDeleteOptions(deleteOptions);
request.setDeletion(deleteArray);
request.setTransferCredentialEndpoint(delegateCredential(host, port));
```

- Now contact the RFT factory and create an RFT resource:

```

public static EndpointReferenceType createRFT(String rftFactoryAddress,
      BaseRequestType request)
throws Exception {
    endpoint = new URL(rftFactoryAddress);
    factoryPort = rftFactoryLocator
        .getReliableFileTransferFactoryPortTypePort(endpoint);
    CreateReliableFileTransferInputType input =
        new CreateReliableFileTransferInputType();
    //input.setTransferJob(transferType);
    if(request instanceof TransferRequestType) {
        input.setTransferRequest((TransferRequestType)request);
    } else {
        input.setDeleteRequest((DeleteRequestType)request);
    }
    Calendar termTime = Calendar.getInstance();
    termTime.add(Calendar.HOUR, 1);
    input.setInitialTerminationTime(termTime);
    setSecurity((Stub)factoryPort);
    CreateReliableFileTransferOutputType response = factoryPort
        .createReliableFileTransfer(input);

    return response.getReliableTransferEPR();
}

```

- Now contact the RFT service Implementation and call start to actually start the transfer:

```

ReliableFileTransferPortType rft = rftLocator
    .getReliableFileTransferPortTypePort(rftepr);
setSecurity((Stub)rft);

//For secure notifications
subscribe(rft);
System.out.println("Subscribed for overall status");
//End subscription code
Calendar termTime = Calendar.getInstance();
termTime.add(Calendar.MINUTE, TERM_TIME);
SetTerminationTime reqTermTime = new SetTerminationTime();
reqTermTime.setRequestedTerminationTime(termTime);
System.out.println("Termination time to set: " + TERM_TIME
    + " minutes");
SetTerminationTimeResponse termRes = rft
    .setTerminationTime(reqTermTime);
StartOutputType startresp = rft.start(new Start());

```

Chapter 5. APIs

1. Programming Model Overview

The Reliable Transfer Service (RFT) is a WSRF based service that provides interfaces for controlling and monitoring third party file transfers using GridFTP servers. The client controlling the transfers (in this case RFT) is hosted inside of a Grid service so it can be managed using the soft state model. It is essentially a reliable and recoverable version of the GT2 `globus-url-copy` tool and more. In GT 4.2.0, RFT can also perform file deletion and recursive directory deletion operations. It is also used by GRAM to perform all the staging operations and cleanup operations.

2. Component API

Some relevant APIs:

- [Service API](#)¹
- [Common API](#)²
- [Client API](#)³

Chapter 6. Services and WSDL

1. Protocol overview

The RFT service implementation in GT 4.2.0 uses standard SOAP messages over HTTP to submit and manage a set of 3rd party GridFTP transfers and to delete files using GridFTP. The user creates an RFT resource by submitting a list of URL pairs of files that need to be transferred/deleted to the RFT Factory service. The user also specifies the time to live for the resource the user is creating to the GT 4.2.0 container in which RFT is deployed and configured. The resource is created after the user is properly authorized and authenticated. RFT service implementation exposes operations to control and manages the transfers (the resource). The operations exposed by both the RFT factory and the RFT service are briefly described below. The resource the user created also exposes the state of the transfer as a resource property to which the user can either subscribe for changes or poll for the changes in state periodically using standard command line clients.

2. Operations

Please find below operations of both RFT Factory and RFT Service Implementation.

2.1. RFT Factory Service

Used to create a Reliable File Transfer resource. The operations exposed by the factory are as follows:

- `createReliableFileTransfer`: Creates a Reliable File Transfer resource.
 - Input Parameters: Initial Termination time, Transfer Request or Delete Request.
 - Output parameters: Termination time, Current time, Endpoint reference of the Resource created. This should be stored by the user, as it is needed to query the status of the resource and to perform any further operations on the resource.
 - Fault: `createReliableFileTransferFault`.

2.2. RFT Service

Used to manage the Resource created using the RFT Factory Service. The operations exposed by the service are as follows:

- `start`: Starts executing the transfers/deletes.
 - Input Parameters: None
 - Output Parameters: None
 - Fault: `RepeatedlyStartedFault`
- `getStatus`: To get the status of a particular file.
 - Input Parameters: A source URL of the file that is part of the request.
 - Output Parameters: `Transfer Status Type`
 - Fault: `RFTDatabaseFault`

- `getStatusSet`: To get the status of a set of files in a request.
 - Input Parameters: `int` from (the relative position of the transfer in the request) and `int` offset (the number of files queried).
 - Output Parameters: An array of `TransferStatusType`.
 - Fault: `RFTDatabaseFault`
- `cancel`: To cancel a transfer that is part of a resource.
 - Input Parameters: `int` from (the relative position of the transfer in the request) and `int` to.
 - Output Parameters: None
 - Fault: `RFTDatabaseFault`

3. RFT Resource Properties

The resource properties of RFT Factory (which acts both as a resource and a service at the same time) and RFT Resource are found below:

3.1. RFT Factory Resource Properties

- `ActiveResourceInstances`: A dynamic resource property of the total number of active RFT resources in the container at a given point of time.
- `TotalNumberOfTransfers`: A dynamic resource property of the total number of transfers/deletes performed since the RFT service was deployed in this container.
- `TotalNumberOfActiveTransfers`: A dynamic resource property of the number of active transfers across all rft resources in a container at a given point of time.
- `TotalNumberOfBytesTransferred`: A dynamic resource property of the total number of bytes transferred by all RFT resources created since the deployment of the service.
- `RFTFactoryStartTime`: Time when the service was deployed in the container. Used to calculate uptime.
- `DelegationServiceEPR`: The end point reference of the Delegation resource that holds the delegated credential used in executing the resource.

3.2. RFT Resource Properties

- `OverallStatus`: This is a complex type providing the overall status of an RFT resource by providing the number of transfers pending, active, finished, retrying, failed, and cancelled. Each of these values can be obtained by invoking `getTransfers(Finished/Active/Failed/Restarted/Pending/Cancelled)` on `OverallStatus` Resource Property. Note that this Resource Property gets updated every time one of the transfers changes state, so there can be and will be more than one update in the life time of a RFT resource if you subscribe to this RP. This Resource Property also includes the last fault (if thrown) from a transfer and can be accessed by invoking `getFault` on `OverallStatus`. This will indicate why a transfer has failed.
- `RequestStatus`: This is a complex type resource property providing the status of an RFT resource in the form of `Pending/Active/Done/Failed`. The status can be obtained from `RequestStatusType` by invoking `getRequestStatus()`. This will result in one of four status strings (`Pending/Active/Done/Failed/Cancelled`). This RP also contains a fault

that denotes the last fault in a RFT resource and can be accessed by invoking `getFault()`. If a client is subscribed to this RP, there will be only be 2 updates in the life time of an RFT resource (Pending->Active->Done, Pending->Active->Failed, Pending->Active->Cancelled, and Pending->Cancelled).

- `TotalBytes`: This provides the total number of bytes transferred by the resource.
- `TotalTime`: This provides the total time taken to transfer the above-mentioned total bytes.

4. Faults

Faults from the RFT Factory Service and RFT Service can be found below:

4.1. RFT Factory Service

- `createReliableFileTransferFault`: All the errors encountered during the creation of the RFT resource are mapped to this fault. Any security related errors are caught before the factory and are thrown to the user/client.

4.2. RFT Service

- `RepeatedlyStartedFault`: This is raised if a client calls start more than once on a resource.
- `RFTDatabaseFault`: This is thrown when the service is unable to find the resource the user/client is querying for.

5. WSDL and Schema Definition

- [Reliable Transfer Factory Port Type](#)¹
- [Reliable Transfer Port Type](#)²

You can find links to all the RFT schemas [here](#)³.

RFT Commands

DRAFT

Name

rft -- Submit and monitor a 3rd party GridFTP transfer

rft

Tool description

Submits a transfer to the Reliable File Transfer Service and prints out the status of the transfer on the console.

Command syntax and options

```
rft [-h <host-ip of the container defaults to localhost>
-r <port, defaults to 8080>
-l <lifetime for the resource default 60mins>
-m <security mechanism. 'msg' for secure message or 'conv' for
  secure conversation and 'trans' for transport. Defaults to
  secure transport.>
-p <protection type, 'sig' signature and 'enc' encryption,
  defaults to signature >
-z <authorization mechanism can be self or host. default self>
-file <file to write EPR of created Reliable File Transfer Resource]>
-f <path to the file that contains list of transfers>
```

This is a sample transfer file that the command-line client will be able to parse. It can also be found in **\$GLOBUS_LOCATION/share/globus_wsrf_rft_client/** along with other samples for directory transfers and deletes (lines starting with # are comments):

```
This option when it is set to true means to perform transfer in binary
form, if it is set to false transfer is done in ASCII. Default is binary.
true
#Block size in bytes that is transferred. Default is 16000 bytes.
16000
#TCP Buffer size in bytes
#Specifies the size (in bytes) of the TCP buffer to be used by the underlying
ftp data channels. This is critical to good performance over the WAN. Use the
bandwidth-delay product as your buffer size.

16000

#Notpt (No thirdPartyTransfer): turns third-party transfers off is this option
is set to false (on if set to true).
Site firewall and/or software configuration may prevent a connection
between the two servers (a third party transfer). If this is the case,
RFT will "relay" the data. It will do a GET from the source and a PUT to
the destination. This obviously causes a performance penalty, but will allow
you to complete a transfer you otherwise could not do.

false

#Number of parallel streams: Specifies the number of parallel data connections
that should be used.
```

1

```
#Data Channel Authentication (DCAU): Turns off data channel authentication for
FTP transfers is set to false.(the default is true to authenticate the data
channel).
```

```
true
```

```
# Concurrency of the request: Number of files that you want to transfer at any
given point. Default is set to one.
```

```
1
```

```
#Grid Subject name of the source gridftp server. This is used for Authorization
purposes. If the source gridftp server is running with host credentials you can specify "n
/DC=org/DC=doe grids/OU=People/CN=Ravi Madduri 134710
```

```
#Grid Subject name of the destination gridftp server. This is used for Authorization purpo
credentials you can specify "null" here. By default Host authorization is done.
```

```
/DC=org/DC=doe grids/OU=People/CN=Ravi Madduri 134710
```

```
#Transfer all or none of the transfers: This option if set to true will make RFT
to clean up ( delete ) all the transfers that have been done already if one of the transfe
```

```
false
```

```
#Maximum number of retries: This is number of times RFT retries a transfer failed with a n
```

```
10
```

```
#Source/Dest URL Pairs: gsiftp urls of source followed by destination.
```

```
If directory is to be recursively transferred the source gsiftp url and
destination gsiftp url should end with "/". Currently RFT supports Directory -
Directory, File - Directory, File - File transfers. There can be more URL pairs
and all of them use the same options as above for performing the transfer.
```

```
gsiftp://localhost:5678/tmp/rftTest.tmp
```

```
gsiftp://localhost:5678/tmp/rftTest_Done.tmp
```

Limitations

This command line client is very simple and does not do any intelligent parsing of various command line options or of the options in the sample transfer file. It works fine if used in the way documented here. For more information on all these options please refer to the [documentation of globus-url-copy](#). Also, please note that the maximum number of transfers the command-line client can process before running out of memory is ~21K with the default JVM heap size, which was 64M in our tests. Please look at [Performance Reports](#)¹ for more details.

¹ ../rft_scalability_3_9_4.doc

Name

globus-crft -- Command-line client to delete files using RFT

globus-crft

Tool description

This distribution contains a client to the RFT service written in C. RFT is the reliable transfer server. It allows clients to submit URL transfer requests to a persistent service which will perform the transfers on behalf of the client.

Options

-a --all-or-none <on off>	Enable all or none transfer: default off.
-con --concurrent <int>	The number of simultaneous transfers.
-C --cancel	Cancel a transfer.
-c --create	Create a new RFT service.
-del --delete	Delete a URL.
-ds --destination-subject <subject>	The expected domain name of the destination GridFTP server.
-d --destroy	Destroy the server. If used with <code>-monitor</code> , wait until completion and then destroy.
-D --done	Return the current status of the transfer in the exit code: <ul style="list-style-type: none"> • 0=Done • 1=Active • 2=Pending • 3=Cancelled • 4=Failed
-ef --epr-file <path>	Path to the EPR file. If used with <code>--create</code> the EPR is written to this location. In all other cases the EPR is read from this location.
-ez --easy	Create, submit, and wait for the transfer to complete. The job is started with some standard options.
-e --factory <contact>	The endpoint to contact when creating a server. Used with <code>--create</code> .
-f --transfer-file <path>	A path to a file that contains the source destination URL pairs.
-gS --getStatusSet <int> <int>	Get the status of all the transfer requests in the range.
-g --getStatus <source url>	Get the status of the given source url.

`-h` | `--help` Print usage information.

FIXME - finish converting to variable list:

`-ms` | `--message-security` `<[sig] | [conv] | [trans]>`
Security mechanism. 'msg' for secure message, 'conv' for secure conversation, 'trans' for transport. The default is trans.

`-m` | `--monitor` Wait for the service to complete, and receive status updates.

`-os` | `--getOverallStatus` Get the overall status.

`-p` | `--protection` `<[sig] | [enc]>`
Protection type. 'sig' for signature, 'enc' for encryption. The default is 'sig'.

`-P` | `--parallel` `<int>` The number of parallel sockets to use with each transfer.

`-q` | `--quiet` Write no output.

`-rs` | `--getRequestStatus` Get the request status.

`-r` | `--retries` Number of retries

`-S` | `--subject` `<subject>` The expected domain name of both the source and destination GridFTP servers.

`-ss` | `--source-subject` `<subject>`
The expected domain name of the source GridFTP server.

`-s` | `--submit` Start the RFT service

`-tb` | `--tcp-bs` `<int>` The TCP buffer size to use with each transfer.

`-ttl` | `--termination-time` `<int>`
Set the lifetime of the service.

`-v` | `--version` Print version information.

`-vb` | `--verbose` Display much more output.

`-xi` | `--xml-input` `<path>` Read the request description from the given xml description.

`-xo` | `--xml-output` `<path>` Write the request description to the given file location in xml format.

`-z` | `--authz` `<[self] | [host] | [id <subject>]>`
Authorization. 'self', 'host', or 'id <DN>'.

Limitations

No limitations exist with this command line tool.

Name

rft-delete -- Command-line client to delete files using RFT

rft-delete

Tool description

This command-line tool is used to submit a list of files to be deleted.

Command and options

```
rft-delete [-h <host-ip of the container default localhost>
-r <port, defaults to 8080>
-l <lifetime for the resource default 60mins>
-m <security mechanism. 'msg' for secure message or 'conv' for
  secure conversation and 'trans' for transport. Defaults to
  secure transport.>
-p <protection type, 'sig' signature and 'enc' encryption,
  defaults to signature >
-z <authorization mechanism can be self or host. default self>
-file <file to write EPR of created Reliable File Transfer Resource]>
-f <path to the file that contains list of transfers>
```

This is a sample file that the command line client will be able to parse, and it can also be found in **\$GLOBUS_LOCATION/share/globus_wsrf_rft_client/** along with other samples for directory transfers and deletes (lines starting with # are comments):

```
# Subject name (defaults to host subject)
  /DC=org/DC=doegrids/OU=People/CN=Ravi Madduri 134710
  gsiftp://localhost:5678/tmp/rftTest_Done.tmp
  gsiftp://localhost:5678/tmp/rftTest_Done1.tmp
```

Limitations

No limitations exist with this command line tool.

Chapter 7. RFT transfer request

1. Request Schema

Please go [here](#)¹ to view the entire RFT transfer request schema documentation.

2. Request Options

2.1. General Options

These options are set in the `transferRequest`² and `deleteRequest`³ elements and apply similarly for each.

- *concurrency*

This denotes number of files in the request that needs to be transferred at one time.

- *maxAttempts*

Maximum number of attempts after transient errors to execute the transfer or deletion before giving up and raising an error.

- *finishBy*

(Not Implemented) In future versions of RFT this will be used to enforce time constraints on a transfer.

2.2. Transfer Options

These options are set in the `rftOptions` element (see `RFTOptionsType`⁴ for more details) and are specific to file transfers. They can be specified as defaults for all transfers under the `transferRequest`⁵ element, and/or individually under each `transfer` element (see `TransferType`⁶ for more details):

```
<transferRequest>
  <transfer>...</transfer>
  <rftOptions>
    <!-- option elements here -->
  </rftOptions>
</transferRequest>
```

AND/OR

```
<transferRequest>
  <transfer>
```

¹ ../rft_job_description.html

² ../rft_job_description.html#element_transferRequest

³ ../rft_job_description.html#element_deleteRequest

⁴ ../rft_job_description.html#type_RFTOptionsType

⁵ ../rft_job_description.html#element_transferRequest

⁶ ../rft_job_description.html#type_TransferType

```
    ...
    <sourceUrl>
    <destinationUrl>
    ...
    <rftOptions>
      <!-- option elements here -->
    </rftOptions>
  </transfer>
</transferRequest>
```

- *binary*
Transfer as a binary file. Default is "true".
- *blockSize*
Specifies the size of the data blocks to use in the transfer.
- *tcpBufferSize*
Specifies the TCP buffer size used for the transfer.
- *notpt*
If set to "true", third-party transfer mode will not be use. Instead, a client thread will be started that will GET data from the source server and and PUT data to the destination server. Default is "false".
- *parallelStreams*
Specifies the number of parallel streams to use during the transfer. Default is 1.
- *dcau*
Specifies whether or not to use data channel authentication. Default is true.
- *subjectName*
Specifies the credential subject to use for authenticating both the source and destination servers.
- *destinationSubjectName*
Specifies the credential subject to use for authenticating the destination server.
- *sourceSubjectName*
Specifies the credential subject to use for authenticating the source server.
- *userName*
Specifies the username to be used to perform the transfer which sometimes may not be the same as transfer requester.

2.3. Deletion Options

These options are set in the `deleteOptions` element (see [DeleteOptionsType](#)⁷ for more details), and are specific to file deletions. They can be specified as defaults for all deletions under the `deleteRequest`⁸ element, and/or individually under each `deletion` element (see [DeleteType](#)⁹ for more details):

```
<deleteRequest>
  <deletion>...</deletion>
  <deleteOptions>
    <!-- option elements here -->
  </deleteOptions>
</deleteRequest>
```

AND/OR

```
<deleteRequest>
  <deletion>
    ...
    <file>
      <deleteOptions>
        <!-- option elements here -->
      </deleteOptions>
    </deletion>
  </deleteRequest>
```

- *subjectName*
Specifies the credential subject to use for authenticating the target server.
- *userName*
Specifies the username to be used to perform the deletion.

⁷ ../rft_job_description.html#type_DeleteOptionsType

⁸ ../rft_job_description.html#element_deleteRequest

⁹ ../rft_job_description.html#type_DeleteType

Chapter 8. Configuring RFT

1. Configuration overview

RFT has the following prerequisites:

- [Java WS Core](#) - This is built and installed in a [Installing GT 4.2.0](#).
- A host certificate (see [Installing GT 4.2.0](#)).
- [GridFTP](#) - GridFTP performs the actual file transfer and is built and installed in a [Installing GT 4.2.0](#).
- PostgreSQL - PostgreSQL is used to store the state of the transfer to allow for restart after failures. The interface to PostgreSQL is JDBC, so any DBMS that supports JDBC can be used, although no others have been tested. For instructions on configuring the PostgreSQL database for RFT, see below. .

2. Syntax of the interface

The security of the service can be configured by modifying the [security descriptor](#). It allows for configuring the credentials that will be used by the service, type of authentication and authorization that needs to be enforced. By default, the following security configuration is installed:

- Credentials set for use by the container are used. If they aren't specified, default credentials are used.
- GSI Secure conversation authentication is enforced for all methods.

Note: Changing the required authentication and authorization method will require suitable changes to the clients that contact this service.

To alter the security descriptor configuration, refer to [security descriptor](#). The file to be altered is `$GLOBUS_LOCATION/etc/globus_wsrf_rft/security-config.xml`.

3. Optional configuration: configuring the PostgreSQL database

PostgreSQL (version 7.1 or greater) can be used with RFT but is no longer a requirement. You can either use the packages which came with your operating system (RPMs, DEBs, ...) or build from source. We used PostgreSQL version 7.3.2 for our testing and the following instructions are good for the same.

1. Install PostgreSQL. Instructions on how to install/configure PostgreSQL can be found [here](#)¹.
2. Configure the postmaster daemon so that it accepts TCP connections. This can be done by adding the "-o -i" switch to the postmaster script (This is either the init.d script found in `/etc/init.d/postgresql` or `/var/lib/`, depending on how you installed PostgreSQL). Follow the instructions [here](#)² to start the postmaster with the -i option.
3. You will now need to create a PostgreSQL user that will connect to the database. This is usually the account under which the container is running. You can create a PostgreSQL user by running the following command: `su postgres; createuser globus`. If you get the following error: `psql: could not connect to`

¹ <http://www.postgresql.org/docs/manuals/>

² <http://www.postgresql.org/docs/7.4/static/postmaster-start.html>

server: No such file or directory Is the server running locally and accepting connections on Unix domain socket "/tmp/.s.PGSQL.5432"? this generally means that either your postmaster is not started with the -i option or you didn't restart the postmaster after the above mentioned step.

4. Now you need to set security on the database you are about to create. You can do it by following the steps below:

```
sudo vi /var/lib/pgsql/data/pg_hba.conf and append the following line to the file:
```

```
host rftDatabase "username" "host-ip" 255.255.255.255 md5 Note: use crypt instead of md5 if you are using PostgreSQL 7.3 or earlier.
```

```
sudo /etc/init.d/postgresql restart
```

5. To create the database that is used for RFT run (as user globus): `createdb rftDatabase`.
6. To populate the RFT database with the appropriate schemas run: `psql -d rftDatabase -f $GLOBUS_LOCATION/share/globus_wsrft_rft/rft_schema.sql`. Now that you have created a database to store RFT's state, the following steps configure RFT to find the database:
7. Open `$GLOBUS_LOCATION/etc/globus_wsrft_rft/jndi-config.xml`.
8. Find the `dbConfiguration` section under the `ReliableFileTransferService <service>` section.
9. Change the `connectionString` to point to the machine on which you installed PostgreSQL and to the name of the database you used in step 2. If you installed PostgreSQL on the same machine as your Globus install, the default should work fine for you.
10. Change the `userName` to the name of the user who owns/created the database and do the same for the password (it also depends on how you configured your database).
11. Don't worry about the other parameters in the section. The defaults should work fine for now.
12. Edit the configuration section under `ReliableFileTransferService`. There are two values that can be edited in this section:
13.
 - `backOff`: Time in seconds you want RFT to backoff before a failed transfer is retried by RFT. The default should work fine for now.
 - `maxActiveAllowed`: This is the number of transfers the container can do at given point. The default should be fine for now.

4. Optional configuration: configuring the MySQL database

If you prefer MySQL to Postgres or derby you can use it with RFT instead. Instructions on how to this can be found at [here](http://www.globus.org/toolkit/docs/4.2/4.2.0/data/rft/admin/rft-admin-mysql.html).³

³ <http://www.globus.org/toolkit/docs/4.2/4.2.0/data/rft/admin/rft-admin-mysql.html>

5. RFT auto-registration with default WS MDS Index Service

With a default GT 4.2.0 installation, the RFT service is automatically registered with the default WS MDS Index Service running in the same container for monitoring and discovery purposes.

There is a jndi resource defined in `$GLOBUS_LOCATION/etc/globus_wsrf_rft/jndi-config.xml` as follows :

```
<resource name="mdsConfiguration"
  type="org.globus.wsrfl.impl.servicegroup.client.MDSConfiguration">
  <resourceParams>
    <parameter>
      <name>reg</name>
      <value>true</value>
    </parameter>
    <parameter>
      <name>factory</name>
      <value>org.globus.wsrfl.jndi.BeanFactory</value>
    </parameter>
  </resourceParams>
</resource>
```

To configure the automatic registration of RFT to the default WS MDS Index Service, change the value of the parameter `<reg>` as follows:

- `true` turns on auto-registration; this is the default in GT 4.2.0.
- `false` turns off auto-registration.

5.1. Configuring resource properties

By default, the following resource properties (from the RFT Factory Resource) are sent to the default Index Service:

- `ActiveResourceInstances`: A dynamic resource property of the total number of active RFT resources in the container at a given point of time.
- `TotalNumberOfTransfers`: A dynamic resource property of the total number of transfers/deletes performed since the RFT service was deployed in this container.
- `TotalNumberOfActiveTransfers`: A dynamic resource property of the number of active transfers across all rft resources in a container at a given point of time.
- `TotalNumberOfBytesTransferred`: A dynamic resource property of the total number of bytes transferred by all RFT resources created since the deployment of the service.
- `RFTFactoryStartTime`: Time when the service was deployed in the container. Used to calculate uptime.
- `DelegationServiceEPR`: The end point reference of the Delegation resource that holds the delegated credential used in executing the resource.

You can configure which resource properties are sent in RFT's registration.xml file, \$GLOBUS_LOCATION/etc/globus_wsrft_rft/registration.xml. The following is the relevant section of the file:

```
<Content xsi:type="agg:AggregatorContent"
  xmlns:agg="http://mds.globus.org/aggregator/types">

  <agg:AggregatorConfig xsi:type="agg:AggregatorConfig">

    <agg:GetMultipleResourcePropertiesPollType
      xmlns:rft="http://www.globus.org/namespaces/2004/10/rft">
      <!-- Specifies that the index should refresh information
        every 60000 milliseconds (once per minute) -->
      <agg:PollIntervalMillis>60000</agg:PollIntervalMillis>

      <!-- specifies that all Resource Properties should be
        collected from the RFT factory -->

      <agg:ResourcePropertyNames>rft:TotalNumberOfBytesTransferred</agg:ResourcePropertyNames>
      <agg:ResourcePropertyNames>rft:TotalNumberOfActiveTransfers</agg:ResourcePropertyNames>
      <agg:ResourcePropertyNames>rft:RFTFactoryStartTime</agg:ResourcePropertyNames>
      <agg:ResourcePropertyNames>rft:ActiveResourceInstances</agg:ResourcePropertyNames>

      <agg:ResourcePropertyNames>rft:TotalNumberOfTransfers</agg:ResourcePropertyNames>

    </agg:GetMultipleResourcePropertiesPollType>
  </agg:AggregatorConfig>
</agg:AggregatorData/>
</Content>
```

6. Registering RFT manually with default WS MDS Index Service

If a third party needs to register an RFT service manually, see [Registering with mds-servicegroup-add](#) in the WS MDS Aggregator Framework documentation.

Chapter 9. Environment variable interface

1. Environmental variables for RFT

The only environment variable that needs to be set for RFT is `GLOBUS_LOCATION`, in order to run the command line clients, which should be set to the location of the globus installation.

DRAFT

Chapter 10. Debugging

Log output from RFT is a useful tool for debugging issues. Because RFT is built on top of Java WS Core, developer debugging is the same as described in [Chapter 10. Debugging](#). For information about sys admin logs, see [Chapter 7. Debugging](#).

1. Development Logging in Java WS Core

The following information applies to Java WS Core and those services built on it.

Logging in the Java WS Core is based on the [Jakarta Commons Logging](#)¹ API. Commons Logging provides a consistent interface for instrumenting source code while at the same time allowing the user to plug-in a different logging implementation. Currently we use [Log4j](#)² as a logging implementation. Log4j uses a separate configuration file to configure itself. Please see Log4j documentation for details on the [configuration file format](#)³.

1.1. Configuring server side developer logs

Server side logging can be configured in `$GLOBUS_LOCATION/container-log4j.properties`, when the container is stand alone container. For tomcat level logging, refer to [Logging for Tomcat](#)⁴. The logger `log4j.appender.A1` is used for developer logging and by default writes output to the system output. By default it is set for all warnings in the Globus Toolkit package to be displayed.

Additional logging can be enabled for a package by adding a new line to the configuration file. Example:

```
#for debug level logging from org.globus.package.FooClass
log4j.category.org.globus.package.name.FooClass=DEBUG
#for warnings from org.some.warn.package
log4j.category.org.some.warn.package=WARN
```

1.2. Configuring client side developer logs

Client side logging can be configured in `$GLOBUS_LOCATION/log4j.properties`. The logger `log4j.appender.A1` is used for developer logging and by default writes output to the system output. By default it is set for all warnings in the Globus Toolkit package to be displayed.

2. Enable Debug Logging in RFT

A standard way to debug RFT is to make the container print out more verbose error messages. You can do this with the following steps:

Edit `$GLOBUS_LOCATION/container-log4j.properties` and add following line to it:

```
log4j.category.org.globus.transfer=DEBUG
```

¹ <http://jakarta.apache.org/commons/logging/>

² <http://logging.apache.org/log4j/>

³ [http://logging.apache.org/log4j/docs/api/org/apache/log4j/PropertyConfigurator.html#doConfigure\(java.lang.String,org.apache.log4j.spi.LoggerRepository\)](http://logging.apache.org/log4j/docs/api/org/apache/log4j/PropertyConfigurator.html#doConfigure(java.lang.String,org.apache.log4j.spi.LoggerRepository))

⁴ <http://tomcat.apache.org/tomcat-5.5-doc/logging.html>

. For more verbosity add

```
log4j.category.org.globus.ftp=DEBUG
```

, which will print out Gridftp messages too.

DRAFT

Chapter 11. Troubleshooting

For a list of common errors in GT, see [Error Codes](#).

1. Errors

Table 11.1. Reliable File Transfer (RFT) Errors

Error Code	Definition	Possible Solutions
Error creating RFT Home: Failed to connect to database ... Until this is corrected all RFT request will fail and all GRAM jobs that require staging will fail	This occurs when you start the container if RFT is not configured properly to talk to a PostgreSQL database.	The usual cause is that Postmaster is not accepting TCP connections, which means that you must restart Postmaster with the <code>-i</code> option (see Configuring RFT).

2. RFT fault-tolerance and recovery

RFT uses PostgreSQL to check-point transfer state in the form of restart markers and recover from transient transfer failures, using retry mechanism with exponential backoff, during a transfer. RFT has been tested to recover from source and/or destination server crashes during a transfer, network failures, container failures (when the machine running the container goes down), file system failures, etc. RFT Resource is implemented as a PersistentResource, so ReliableFileTransferHome gets initialized every time a container gets restarted. Please find a more detailed description of fault-tolerance and recovery in RFT below:

- **Source and/or destination GridFTP failures:** In this case RFT retries the transfer for a configurable number of maximum attempts with exponential backoff for each retry (the backoff time period is configurable also). If a failure happens in the midst of a transfer, RFT uses the last restart marker that is stored in the database for that transfer and uses it to resume the transfer from the point where it failed, instead of restarting the whole file. This failure is treated as a container-wide backoff for the server in question. What this means is that all other transfers going to/from that server, across all the requests in a container, will be backed off and retried. This is done in order to prevent further failures of the transfers by using knowledge available in the database.
- **Network failures:** Sometimes this happens due to heavy load on a network or for any other reason packets are lost or connections get timed out. This failure is considered a transient failure and RFT retries the transfer with exponential backoff for that particular transfer (and not the whole container, as with the source and/or destination GridFTP failures).
- **Container failures:** These type of failures occur when the machine running the container goes down or if the container is restarted with active transfers. When the container is restarted, it restarts ReliableTransferHome, which looks at the database for any active RFT resources and restarts them.

2.1. Failure modes that are not addressed:

- Running out of disk space for the database.

GT 4.2.0 Reliable File Transfer (RFT) Service: Migration Guide

Table of Contents

1. Migrating RFT from GT4.0 to GT4.2	1
2. Migrating RFT from GT4	1
3. Migrating RFT from GT3	1
4. Migrating RFT from GT2	1

<titleabbrev>Migrating Guide</titleabbrev>

The following provides available information about migrating from previous versions of the Globus Toolkit.

1. Migrating RFT from GT4.0 to GT4.2

RFT no longer requires an externally running PostgreSQL server to be running. Included with the distribution of RFT is an embedded derby database. The database is automatically installed and configured at the time RFT is installed.

2. Migrating RFT from GT4

The public interfaces to Java WS Core (on which RFT is based) have changed and are not backwards compatible. For information on updating your services, see [Section 1, “Updating higher level services”](#).

3. Migrating RFT from GT3

The RFT implementations in GT4 and GT3 are not interoperable, as they are built on different GT core implementations. In order to migrate to GT4 RFT you should follow the installation instructions, which can be found in [Installing GT 4.2.0](#).

4. Migrating RFT from GT2

This does not apply to RFT.

9. Associated Standards	6
10. For More Information	7

<titleabbrev>Release Notes</titleabbrev>

1. Component Overview

The Reliable Transfer Service (RFT) Service implementation in GT 4.2.0 uses standard SOAP messages over HTTP to submit and manage a set of 3rd party GridFTP transfers and deletion of files and directories using GridFTP. The service also provides an interface to control various transfer parameters of the GridFTP control channel like TCP buffer size, parallel streams, DCAU etc. The user creates a RFT resource by submitting a Transfer Request (consisting of a set of third-party gridftp transfers) to the RFT Factory service. The resource is created after the user is properly authorized and authenticated. RFT service implementation exposes operations to control and manage the transfers (the resource). The resource the user created exposes the state of the transfer as a resource property to which the user can either subscribe for changes or poll for the changes in state periodically using standard WS-RF command line clients and other resource properties.

2. RFT Feature Summary

Features new in GT 4.2.0

Supported Features

- Delete files: Delete a set of files/directories on a GridFTP server.
- Exponential Backoff: Configurable exponential back off before a failed transfer is retried.
- Transfer All or None: If this option is set and one of the transfers in the request fails, RFT will stop transferring the remainder of the request and delete the files that were already transferred successfully.
- Transfer Permissions: File permissions are restored at the destination once the file is transferred successfully. This can be configured to throw a fatal error or a transient error depending on whether the GridFTP server supports the MLST command.
- Configurable number of concurrent transfers per container and per request.

- Better error reporting and faults.
- Database purge of the request and transfers after life time expiration.
- Cumulative (aggregate) Resource Properties on the factory provide some statistical information.
- One status Resource Property for the entire transfer.
- Recursive directory transfers and deletes.
- Parallel streams.
- TCP Buffer Size.
- Third-party directory transfers, file transfers and deletes.
- Data channel authentication (DCAU).
- NoTPT option.
- Different subject names for source and destination GridFTP servers for the authorization mechanism.
- Support for binary/ASCII type of transfers.
- Configurable number of retries for failed transfers per request.
- Block Size in bytes.

Deprecated Features

- None

3. Summary of Changes in RFT

The following changes have occurred for RFT since the last stable release, 4.0.x:

New in RFT 4.2 is a connection caching feature. This allows internal GridFTP connections to be internally cached globally across all service requests. This has shown to be a vast performance increase in the cases where a single users wishes to transfer many URLs, but instead of transferring them in a single request, they put each in one request. Cache helps this case specifically, and is a general optimization for other cases.

The backoff algorithm has been modified. To start with, all errors in communicating with GridFTP servers are considered transient. In the past we considered authorization failures and DNS lookup failures, as well as other similar things as fatal. We have since recognized that even those shall pass, and in some environments those should be expected as a means of controlling load.

Additionally how we back off is different. If a failure is detected we do not try to communicate with the given GridFTP server for a specified amount of time, *or* until some other transfer completes successfully with that server. This allows for optimal use of GridFTP servers that only allow a fixed number of connections at once, and it helps make optimal use of our connection cache.

5. Known Problems

The following problems and limitations are known to exist for RFT at the time of the 4.2.0 release:

5.1. Limitations

Does not compile with JDK 1.3.1.

5.2. Outstanding Issues

- [3121](#)⁴⁶ - The configured maximum allowed active transfers constraint is not enforced.

6. Technology dependencies

RFT depends on the following GT components:

- Java WS Core
- WS Authentication and Authorization
- Delegation Service
- Service Groups
- MDS useful RP

RFT depends on the following 3rd party software:

- Optional : PostgreSQL 7.1 or later. Not tested with 8.0 yet.
- Optional : MySQL

⁴⁰ http://bugzilla.globus.org/globus/show_bug.cgi?id=3110

⁴¹ http://bugzilla.globus.org/globus/show_bug.cgi?id=3091

⁴² http://bugzilla.globus.org/globus/show_bug.cgi?id=3130

⁴⁵ http://bugzilla.globus.org/globus/show_bug.cgi?id=2956

⁴⁶ http://bugzilla.globus.org/globus/show_bug.cgi?id=3121

7. Tested platforms

Tested platforms for RFT:

- Linux
 - Fedora Core 1 i686
 - Fedora Core 3 i686
 - RedHat 7.3 i686
 - RedHat 9 x86
 - Debian Sarge x86
 - Debian 3.1 i686
- Mac OS X
 - Mac OS X 10.3, 10.4

Tested containers for RFT:

- Java WS Core container
- Tomcat 5.0.30

8. Backward compatibility summary

Protocol changes since GT 4.0.x

- Added All or None option, maximum attempts, and finishBy to the transfer request
- Not backwards compatible with the OGSi version

API changes since GT 4.0.x

- None

Exception changes since GT 4.0.x

- None

Schema changes since GT 4.0.x

- WSDL changes to work with the new Java WS Core

9. Associated Standards

Associated standards for RFT:

- WSRF⁴⁷

⁴⁷ <http://docs.oasis-open.org/wsrf/2004/06/wsrf-WS-ServiceGroup-1.2-draft-02.pdf>

- [WS-Addressing](#)⁴⁸
- [WS-Security](#)⁴⁹

10. For More Information

See [Reliable File Transfer \(RFT\) Service](#) for more information about this component.
